# 1 Unique, Stable Target and Steady State Points

This appendix proves Theorems 2-3 and:

**Lemma 1.** If  $\check{m}$  and  $\hat{m}$  both exist, then  $\check{m} \leq \hat{m}$ .

### 1.1 Proof of Theorem 2

The elements of the proof of Theorem 2 are:

- Existence and continuity of  $\mathbb{E}_t[m_{t+1}/m_t]$
- Existence of a point where  $\mathbb{E}_t[m_{t+1}/m_t] = 1$
- $\mathbb{E}_t[m_{t+1}] m_t$  is monotonically decreasing

## 1.2 Existence and Continuity of $\mathbb{E}_t[m_{t+1}/m_t]$

The consumption function exists because we have imposed sufficient conditions (the WRIC and FVAC; Theorem 1).

Section 2.8 shows that for all t,  $a_{t-1} = m_{t-1} - c_{t-1} > 0$ . Since  $m_t = a_{t-1}\mathcal{R}_t + \boldsymbol{\xi}_t$ , even if  $\boldsymbol{\xi}_t$  takes on its minimum value of 0,  $a_{t-1}\mathcal{R}_t > 0$ , since both  $a_{t-1}$  and  $\mathcal{R}_t$  are strictly positive. With  $m_t$  and  $m_{t+1}$  both strictly positive, the ratio  $\mathbb{E}_t[m_{t+1}/m_t]$  inherits continuity (and, for that matter, continuous differentiability) from the consumption function.

# 1.3 Existence of a point where $\mathbb{E}_t[m_{t+1}/m_t] = 1$ .

This follows from:

- 1. Existence and continuity of  $\mathbb{E}_t[m_{t+1}/m_t]$  (just proven)
- 2. Existence a point where  $\mathbb{E}_t[m_{t+1}/m_t] < 1$
- 3. Existence a point where  $\mathbb{E}_t[m_{t+1}/m_t] > 1$
- 4. The Intermediate Value Theorem

## 1.3.1 Existence of m where $\mathbb{E}_t[m_{t+1}/m_t] < 1$

If RIC holds. Logic exactly parallel to that of Section 3.1 leading to equation (38), but dropping the  $\Phi_{t+1}$  from the RHS, establishes that

$$\lim_{m_t \uparrow \infty} \mathbb{E}_t[m_{t+1}/m_t] = \lim_{m_t \uparrow \infty} \mathbb{E}_t \left[ \frac{\mathcal{R}_{t+1}(m_t - c(m_t)) + \boldsymbol{\xi}_{t+1}}{m_t} \right]$$

$$= \mathbb{E}_t[(R/\boldsymbol{\Phi}_{t+1})\boldsymbol{\mathbf{P}}_R]$$

$$= \mathbb{E}_t[\boldsymbol{\mathbf{P}}/\boldsymbol{\Phi}_{t+1}]$$

$$< 1$$
(1)

where the inequality reflects imposition of the GIC-Nrm (26).

If RIC fails. When the RIC fails, the fact that  $\lim_{m^{\uparrow}_{\infty}} c'(m) = 0$  (see equation (30)) means that the limit of the RHS of (1) as  $m \uparrow \infty$  is  $\overline{\mathcal{R}} = \mathbb{E}_t[\mathcal{R}_{t+1}]$ . In the next step of this proof, we will prove that the combination GIC-Nrm and RIC implies  $\overline{\mathcal{R}} < 1$ .

So we have  $\lim_{m\uparrow\infty} \mathbb{E}_t[m_{t+1}/m_t] < 1$  whether the RIC holds or fails.

## 1.3.2 Existence of m > 1 where $\mathbb{E}_t[m_{t+1}/m_t] > 1$

Paralleling the logic for c in Section 3.2: the ratio of  $\mathbb{E}_t[m_{t+1}]$  to  $m_t$  is unbounded above as  $m_t \downarrow 0$  because  $\lim_{m_t \downarrow 0} \mathbb{E}_t[m_{t+1}] > 0$ .

Intermediate Value Theorem. If  $\mathbb{E}_t[m_{t+1}/m_t]$  is continuous, and takes on values above and below 1, there must be at least one point at which it is equal to one.

1.3.3  $\mathbb{E}_t[m_{t+1}] - m_t$  is monotonically decreasing.

Now define  $\zeta(m_t) \equiv \mathbb{E}_t[m_{t+1}] - m_t$  and note that

$$\zeta(m_t) < 0 \leftrightarrow \mathbb{E}_t[m_{t+1}/m_t] < 1$$

$$\zeta(m_t) = 0 \leftrightarrow \mathbb{E}_t[m_{t+1}/m_t] = 1$$

$$\zeta(m_t) > 0 \leftrightarrow \mathbb{E}_t[m_{t+1}/m_t] > 1,$$
(2)

so that  $\zeta(\hat{m}) = 0$ . Our goal is to prove that  $\zeta(\bullet)$  is strictly decreasing on  $(0, \infty)$  using the fact that

$$\boldsymbol{\zeta}'(m_t) \equiv \left(\frac{d}{dm_t}\right) \boldsymbol{\zeta}(m_t) = \mathbb{E}_t \left[ \left(\frac{d}{dm_t}\right) \left( \mathcal{R}_{t+1}(m_t - c(m_t)) + \boldsymbol{\xi}_{t+1} - m_t \right) \right]$$

$$= \bar{\mathcal{R}} \left( 1 - c'(m_t) \right) - 1.$$
(3)

Now, we show that (given our other assumptions)  $\zeta'(m)$  is decreasing (but for different reasons) whether the RIC holds or fails.

If RIC holds. Equation (16) indicates that if the RIC holds, then  $\underline{\kappa} > 0$ . We show at the bottom of Section 2.9.1 that if the RIC holds then  $0 < \underline{\kappa} < c'(m_t) < 1$  so that

$$\bar{\mathcal{R}}\left(1 - c'(m_t)\right) - 1 < \bar{\mathcal{R}}\left(1 - \underbrace{\left(1 - \mathbf{p}_{\mathsf{R}}\right)}\right) - 1$$

$$= \bar{\mathcal{R}} \mathbf{p}_{\mathsf{R}} - 1$$

$$= \mathbb{E}_t \left[ \frac{\mathsf{R}}{\mathbf{\Phi} \mathbf{\Psi}} \frac{\mathbf{p}}{\mathsf{R}} \right] - 1$$

$$= \mathbb{E}_t \left[ \frac{\mathbf{p}}{\mathbf{\Phi} \mathbf{\Psi}} \right] - 1$$

which is negative because the GIC-Nrm says  $\mathbf{p}_{\Phi} < 1$ .

If RIC fails. Under RIC, recall that  $\lim_{m\uparrow\infty} c'(m) = 0$ . Concavity of the consumption function means that c' is a decreasing function, so everywhere

$$\bar{\mathcal{R}}\left(1 - c'(m_t)\right) < \bar{\mathcal{R}}$$

which means that  $\zeta'(m_t)$  from (3) is guaranteed to be negative if

$$\bar{\mathcal{R}} \equiv \mathbb{E}_t \left[ \frac{\mathsf{R}}{\mathbf{\Phi} \mathbf{\Psi}} \right] < 1. \tag{4}$$

But the combination of the GIC-Nrm holding and the RIC failing can be written:

$$\underbrace{\mathbb{E}_t \left[ \frac{\mathbf{b}}{\mathbf{\Phi} \mathbf{\Psi}} \right]}_{\mathbf{b}_{\mathbf{k}}} < 1 < \underbrace{\frac{\mathbf{b}_{\mathbf{k}}}{\mathbf{R}}}_{\mathbf{k}},$$

and multiplying all three elements by  $R/\mathbf{P}$  gives

$$\mathbb{E}_t \left[ \frac{\mathsf{R}}{\mathbf{\Phi} \mathbf{\Psi}} \right] < \mathsf{R}/\mathbf{P} < 1$$

which satisfies our requirement in (4).

### 1.4 Proof of Theorem 3

The elements of the proof are:

- Existence and continuity of  $\mathbb{E}_t[\Psi_{t+1}m_{t+1}/m_t]$
- Existence of a point where  $\mathbb{E}_t[\mathbf{\Psi}_{t+1}m_{t+1}/m_t] = 1$
- $\mathbb{E}_t[\Psi_{t+1}m_{t+1}-m_t]$  is monotonically decreasing

#### 1.4.1 Existence and Continuity of the Ratio

Since by assumption  $0 < \underline{\Psi} \le \Psi_{t+1} \le \overline{\Psi} < \infty$ , our proof in 1.2 that demonstrated existence and continuity of  $\mathbb{E}_t[m_{t+1}/m_t]$  implies existence and continuity of  $\mathbb{E}_t[\Psi_{t+1}m_{t+1}/m_t]$ .

#### 1.4.2 Existence of a stable point

Since by assumption  $0 < \underline{\Psi} \le \Psi_{t+1} \le \overline{\Psi} < \infty$ , our proof in Subsection 1.2 that the ratio of  $\mathbb{E}_t[m_{t+1}]$  to  $m_t$  is unbounded as  $m_t \downarrow 0$  implies that the ratio  $\mathbb{E}_t[\Psi_{t+1}m_{t+1}]$  to  $m_t$  is unbounded as  $m_t \downarrow 0$ .

The limit of the expected ratio as  $m_t$  goes to infinity is most easily calculated by modifying the steps for the prior theorem explicitly:

$$\lim_{m_{t}\uparrow\infty} \mathbb{E}_{t}[\boldsymbol{\Psi}_{t+1}m_{t+1}/m_{t}] = \lim_{m_{t}\uparrow\infty} \mathbb{E}_{t} \left[ \frac{\boldsymbol{\Phi}_{t+1} \left( (\mathsf{R}/\boldsymbol{\Phi}_{t+1}) \mathsf{a}(m_{t}) + \boldsymbol{\xi}_{t+1} \right) / \boldsymbol{\Phi}}{m_{t}} \right]$$

$$= \lim_{m_{t}\uparrow\infty} \mathbb{E}_{t} \left[ \frac{(\mathsf{R}/\boldsymbol{\Phi}) \mathsf{a}(m_{t}) + \boldsymbol{\Psi}_{t+1} \boldsymbol{\xi}_{t+1}}{m_{t}} \right]$$

$$= \lim_{m_{t}\uparrow\infty} \left[ \frac{(\mathsf{R}/\boldsymbol{\Phi}) \mathsf{a}(m_{t}) + 1}{m_{t}} \right]$$

$$= (\mathsf{R}/\boldsymbol{\Phi}) \boldsymbol{\Phi}_{\mathsf{R}}$$

$$= \boldsymbol{\Phi}_{\boldsymbol{\Phi}}$$

$$< 1$$

$$(5)$$

where the last two lines are merely a restatement of the GIC (19).

The Intermediate Value Theorem says that if  $\mathbb{E}_t[\Psi_{t+1}m_{t+1}/m_t]$  is continuous, and takes on values above and below 1, there must be at least one point at which it is equal to one.

1.4.3  $\mathbb{E}_t[\Psi_{t+1}m_{t+1}] - m_t$  is monotonically decreasing.

Define  $\zeta(m_t) \equiv \mathbb{E}_t[\Psi_{t+1}m_{t+1}] - m_t$  and note that

$$\boldsymbol{\zeta}(m_t) < 0 \leftrightarrow \mathbb{E}_t[\boldsymbol{\Psi}_{t+1}m_{t+1}/m_t] < 1$$

$$\boldsymbol{\zeta}(m_t) = 0 \leftrightarrow \mathbb{E}_t[\boldsymbol{\Psi}_{t+1}m_{t+1}/m_t] = 1$$

$$\boldsymbol{\zeta}(m_t) > 0 \leftrightarrow \mathbb{E}_t[\boldsymbol{\Psi}_{t+1}m_{t+1}/m_t] > 1,$$
(6)

so that  $\zeta(\hat{m}) = 0$ . Our goal is to prove that  $\zeta(\bullet)$  is strictly decreasing on  $(0, \infty)$  using the fact that

$$\boldsymbol{\zeta}'(m_t) \equiv \left(\frac{d}{dm_t}\right) \boldsymbol{\zeta}(m_t) = \mathbb{E}_t \left[ \left(\frac{d}{dm_t}\right) \left( \mathcal{R}(m_t - c(m_t)) + \boldsymbol{\Psi}_{t+1} \boldsymbol{\xi}_{t+1} - m_t \right) \right]$$

$$= (\mathsf{R}/\boldsymbol{\Phi}) \left( 1 - c'(m_t) \right) - 1.$$
(7)

Now, we show that (given our other assumptions)  $\zeta'(m)$  is decreasing (but for different reasons) whether the RIC holds or fails (RIC).

If RIC holds. Equation (16) indicates that if the RIC holds, then  $\underline{\kappa} > 0$ . We show at the bottom of Section 2.9.1 that if the RIC holds then  $0 < \underline{\kappa} < c'(m_t) < 1$  so that

$$\mathcal{R}\left(1 - c'(m_t)\right) - 1 < \mathcal{R}\left(1 - \underbrace{\left(1 - \mathbf{p}_R\right)}_{\underline{\kappa}}\right) - 1$$
$$= (R/\mathbf{\Phi})\mathbf{p}_R - 1$$

which is negative because the GIC says  $\mathbf{p}_{\Phi} < 1$ .

If RIC fails. Under RIC, recall that  $\lim_{m\uparrow\infty} c'(m) = 0$ . Concavity of the consumption function means that c' is a decreasing function, so everywhere

$$\mathcal{R}\left(1 - c'(m_t)\right) < \mathcal{R}$$

which means that  $\zeta'(m_t)$  from (7) is guaranteed to be negative if

$$\mathcal{R} \equiv (\mathsf{R}/\mathbf{\Phi}) < 1. \tag{8}$$

But we showed in Section 2.6 that the only circumstances under which the problem has a nondegenerate solution while the RIC fails were ones where the FHWC also fails (that is, (8) holds).

### 1.5 A Third Measure

A footnote in Section 3 mentions reasons why it may be useful to calculate  $\mathbb{E}_t[\log(\mathbf{m}_{t+1}/\log\mathbf{m}_t)]$ . Here we show that one way of doing that is to calculate a nonlinear adjustment factor for the expectation of the growth factor.

$$\log (\mathbf{m}_{t+1}/\mathbf{m}_t) = \log(\mathbf{\Phi}\mathbf{\Psi}_{t+1}m_{t+1}) - \log m_t$$

$$= \log \mathbf{\Phi}(a_t \mathcal{R} + \mathbf{\Psi}_{t+1}\boldsymbol{\xi}_{t+1}) - \log m_t$$

$$= \log \mathbf{\Phi}(a_t \mathcal{R} + 1 + (\mathbf{\Psi}_{t+1}\boldsymbol{\xi}_{t+1} - 1)) - \log m_t$$

Now define  $\check{m}_{t+1} = a_t \mathcal{R} + 1$ , and compute the expectation:

$$\mathbb{E}_{t}[\log \left(\mathbf{m}_{t+1}/\mathbf{m}_{t}\right)] = \mathbb{E}_{t}\left[\log \mathbf{\Phi}(\breve{m}_{t+1} + \left(\mathbf{\Psi}_{t+1}\mathbf{\xi}_{t+1} - 1\right))\right] - \log m_{t}$$

$$= \log \mathbf{\Phi} + \mathbb{E}_{t}\left[\log \breve{m}_{t+1}\left(1 + \left(\mathbf{\Psi}_{t+1}\mathbf{\xi}_{t+1} - 1\right)\breve{m}_{t+1}^{-1}\right)\right] - \log m_{t}$$

$$= \underbrace{\log \mathbf{\Phi} + \log \breve{m}_{t+1} - \log m_{t}}_{\equiv \log \mathbb{E}_{t}[\mathbf{m}_{t+1}/\mathbf{m}_{t}]} + \mathbb{E}_{t}\left[\log(1 + \left(\mathbf{\Psi}_{t+1}\mathbf{\xi}_{t+1} - 1\right)\breve{m}_{t+1}^{-1}\right)\right]$$

and exponentiating tells us that

$$\exp(\mathbb{E}_t[\log \mathbf{m}_{t+1}/\mathbf{m}_t]) = \mathbb{E}_t[\mathbf{m}_{t+1}/\mathbf{m}_t] \exp(\mathbb{E}_t\left[\log(1 + (\mathbf{\Psi}_{t+1}\boldsymbol{\xi}_{t+1} - 1)\breve{m}_{t+1}^{-1})\right])$$
(9)

and this latter factor is a number that approaches 1 from below as  $m_t$  rises. Thus the expected growth rate of the log is smaller than the log of the growth rate of the expected growth factor. This implies that the m at which 'balanced growth' can be expected in the log,  $\tilde{m}$ , exceeds the corresponding point for the ratio,  $\tilde{m}$ .

Furthermore, in the limit as  $\mathbf{m}_t$  gets arbitrarily large, if the RIC holds and thus  $\underline{\kappa} > 0$ ,  $a_{t+1}$  rises without bound, as does  $\check{m}_{t+1} = a_{t+1}\mathcal{R} + 1$ , so the approximation  $\log(1+\epsilon) \approx \epsilon$  becomes arbitrarily good. Consequently, the last term on the RHS of (9) can be approximated as

$$\mathbb{E}_{t} \left[ \log(1 + (\boldsymbol{\Psi}_{t+1} \boldsymbol{\xi}_{t+1} - 1) \check{m}_{t+1}^{-1}) \right]) \approx \mathbb{E}_{t} \left[ (\boldsymbol{\Psi}_{t+1} \boldsymbol{\xi}_{t+1} - 1) \check{m}_{t+1}^{-1}) \right])$$

$$= 0$$

This demonstrates that

$$\lim_{\mathbf{m}_t \uparrow \infty} \exp(\mathbb{E}_t[\log \mathbf{m}_{t+1}/\mathbf{m}_t]) = \mathbb{E}_t[\mathbf{m}_{t+1}/\mathbf{m}_t]$$
(10)

### 1.6 Proof of Lemma

#### 1.6.1 Pseudo-Steady-State m Is Smaller than Target m

Designate

$$\dot{\mathbf{m}}_{t+1}(a) = 1 + a\mathcal{R} 
 \dot{\mathbf{m}}_{t+1}(a) = 1 + a\mathcal{R}/\underline{\Psi} 
 \bar{\mathcal{R}} > \mathcal{R}$$
(11)

so that we can implicitly define the target and pseudo-steady-state points as

$$\hat{m} = \hat{\mathbf{m}}_{t+1}(\hat{m} - \mathbf{c}(\hat{m}))$$

$$\check{m} = \check{\mathbf{m}}_{t+1}(\check{m} - \mathbf{c}(\check{m}))$$
(12)

Then subtract:

$$\hat{m} - \check{m} = (\hat{a}\underline{\Psi}^{-1} - \check{a}) \mathcal{R} 
= (a(\hat{m})\underline{\Psi}^{-1} - a(\check{m})) \mathcal{R} 
= (a(\hat{m})\underline{\Psi}^{-1} - (a(\hat{m} + \check{m} - \hat{m}))) \mathcal{R} 
\approx (a(\hat{m})\underline{\Psi}^{-1} - (a(\hat{m}) + (\check{m} - \hat{m})a'(\hat{m}))) \mathcal{R} 
(\hat{m} - \check{m})(1 - \underline{a'(\hat{m})\mathcal{R}}) = (\underline{\Psi}^{-1} - 1)\hat{a}\mathcal{R}$$
(13)

The RHS of this equation is strictly positive because  $\underline{\Psi}^{-1} > 1$  and both  $\hat{a}$  and  $\mathcal{R}$  are positive; while on the LHS,  $(1 - \mathcal{R}a') > 0$ . So the equation can only hold if  $\hat{m} - \check{m} > 0$ . That is, the target ratio exceeds the pseudo-steady-state ratio.

1.6.2 The m Achieving Individual Expected-Log-Balanced-Growth Is Smaller than the Individual Pseudo-Steady-State m

Expected log balanced growth occurs when

$$\mathbb{E}_{t}[\log \mathbf{m}_{t+1}] = \log \mathbf{\Phi} \mathbf{m}_{t}$$

$$\mathbb{E}_{t}[\log \mathbf{p}_{t+1} m_{t+1}] = \log \mathbf{\Phi} \mathbf{p}_{t} m_{t}$$

$$\mathbb{E}_{t}[\log \mathbf{\Psi}_{t+1} m_{t+1}] = \log \mathbf{\Phi} m_{t}$$

$$\mathbb{E}_{t}[\log (a(m_{t}) \mathbf{R} + \mathbf{\Psi}_{t+1} \boldsymbol{\xi}_{t+1} \mathbf{\Phi})] = \log \mathbf{\Phi} m_{t}$$

$$\mathbb{E}_{t}[\log (a(m_{t}) \mathcal{R} + \mathbf{\Psi}_{t+1} \boldsymbol{\xi}_{t+1})] = \log m_{t}$$

$$(14)$$

and we call the m that satisfies this equation  $\tilde{m}$ .

Subtract the definition of  $\check{m}$  from that of  $\tilde{m}$ :

$$\exp(\mathbb{E}_t[\log(a(\tilde{m})\mathcal{R} + \Psi_{t+1}\xi_{t+1})]) - (a(\tilde{m})\mathcal{R} + 1) = \tilde{m} - \tilde{m}$$
(15)

Now we use the fact that the expectation of the log is less than the log of the

<sup>&</sup>lt;sup>1</sup>The use of the first order Taylor approximation could be substituted, cumbersomely, with the average of a' over the interval to remove the approximation in the derivations above.

expectation,

$$\exp(\mathbb{E}_t[\log(a(\tilde{m})\mathcal{R} + \Psi_{t+1}\boldsymbol{\xi}_{t+1})]) < (a(\tilde{m})\mathcal{R} + 1)$$
(16)

so

$$\exp(\mathbb{E}_{t}[\log(a(\tilde{m})\mathcal{R}+1)]) - (a(\check{m})\mathcal{R}+1) < \tilde{m} - \check{m}$$

$$(a(\tilde{m})\mathcal{R}+1) - (a(\check{m})\mathcal{R}+1) < \tilde{m} - \check{m}$$

$$(a(\tilde{m}) - a(\tilde{m} + \check{m} - \tilde{m}))\mathcal{R} < \tilde{m} - \check{m}$$

$$(a(\tilde{m}) - (a(\tilde{m}) + (\check{m} - \tilde{m})\bar{a}')\mathcal{R} < \tilde{m} - \check{m}$$

$$(\tilde{m} - \check{m})\bar{a}'\mathcal{R} < \tilde{m} - \check{m}$$

$$\frac{\bar{a}'\mathcal{R}}{\langle \mathbf{p}_{\Phi}} < 1$$

$$(17)$$

where we are interpreting  $\bar{a}'$  as the mean of the value of a' over the interval between  $\tilde{m}$  and  $\check{m}$ .
