1 The Limiting MPC's

For $m_t > 0$ we can define $e_t(m_t) = c_t(m_t)/m_t$ and $a_t(m_t) = m_t - c_t(m_t)$ and the Euler equation (8) can be rewritten

$$\begin{split} \mathbf{e}_{t}(m_{t})^{-\rho} &= \beta \mathbf{R} \, \mathbb{E}_{t} \left[\left(\mathbf{e}_{t+1}(m_{t+1}) \left(\frac{\mathbf{e}_{t+1}(m_{t+1})}{\mathbf{e}_{t}} \mathbf{e}_{t} \mathbf{e$$

Consider the first conditional expectation in (8), recalling that if $\xi_{t+1} > 0$ then $\xi_{t+1} \equiv \theta_{t+1}/(1-\wp)$. Since $\lim_{m\downarrow 0} a_t(m) = 0$, $\mathbb{E}_t[(e_{t+1}(m_{t+1})m_{t+1}\Gamma_{t+1})^{-\rho} \mid \xi_{t+1} > 0]$ is contained within bounds defined by $(e_{t+1}(\underline{\theta}/(1-\wp))\Gamma\underline{\psi}\underline{\theta}/(1-\wp))^{-\rho}$ and $(e_{t+1}(\bar{\theta}/(1-\wp))\Gamma\bar{\psi}\bar{\theta}/(1-\wp))^{-\rho}$ both of which are finite numbers, implying that the whole term multiplied by $(1-\wp)$ goes to zero as m_t^ρ goes to zero. As $m_t \downarrow 0$ the expectation in the other term goes to $\bar{\kappa}_{t+1}^{-\rho}(1-\bar{\kappa}_t)^{-\rho}$. (This follows from the strict concavity and differentiability of the consumption function.) It follows that the limiting $\bar{\kappa}_t$ satisfies $\bar{\kappa}_t^{-\rho} = \beta \wp R^{1-\rho} \bar{\kappa}_{t+1}^{-\rho}(1-\bar{\kappa}_t)^{-\rho}$. Exponentiating by ρ , we can conclude that

$$\bar{\kappa}_t = \wp^{-1/\rho} (\beta R)^{-1/\rho} R (1 - \bar{\kappa}_t) \bar{\kappa}_{t+1}$$

$$\underbrace{\bar{\kappa}_t}_{\bar{\kappa}_t} = \wp^{-1/\rho} (\beta R)^{-1/\rho} R (1 - \bar{\kappa}_t) \bar{\kappa}_{t+1}$$

$$\underbrace{\wp^{1/\rho} R^{-1} (\beta R)^{1/\rho}}_{\equiv \wp^{1/\rho} \mathbf{p}_R} \bar{\kappa}_t = (1 - \bar{\kappa}_t) \bar{\kappa}_{t+1}$$

which yields a useful recursive formula for the maximal marginal propensity to consume:

$$(\mathcal{O}^{1/\rho}\mathbf{P}_{\mathsf{R}}\bar{\kappa}_{t})^{-1} = (1 - \bar{\kappa}_{t})^{-1}\bar{\kappa}_{t+1}^{-1}$$
$$\bar{\kappa}_{t}^{-1}(1 - \bar{\kappa}_{t}) = \mathcal{O}^{1/\rho}\mathbf{P}_{\mathsf{R}}\bar{\kappa}_{t+1}^{-1}$$
$$\bar{\kappa}_{t}^{-1} = 1 + \mathcal{O}^{1/\rho}\mathbf{P}_{\mathsf{R}}\bar{\kappa}_{t+1}^{-1}.$$

As noted in the main text, we need the WRIC (42) for this to be a convergent sequence:

$$0 \le \mathcal{O}^{1/\rho} \mathbf{\tilde{p}}_{\mathsf{R}} < 1,\tag{1}$$

Since $\bar{\kappa}_T = 1$, iterating (1) backward to infinity (because we are interested in the limiting consumption function) we obtain:

$$\lim_{n \to \infty} \bar{\kappa}_{T-n} = \bar{\kappa} \equiv 1 - \mathcal{O}^{1/\rho} \mathbf{P}_{R}$$
 (2)

and we will therefore call $\bar{\kappa}$ the 'limiting maximal MPC.'

The minimal MPC's are obtained by considering the case where $m_t \uparrow \infty$. If the

FHWC holds, then as $m_t \uparrow \infty$ the proportion of current and future consumption that will be financed out of capital approaches 1. Thus, the terms involving ξ_{t+1} in (1) can be neglected, leading to a revised limiting Euler equation

$$\left(m_t \mathbf{e}_t(m_t)\right)^{-\rho} = \beta \mathbf{R} \mathbb{E}_t \left[\left(\mathbf{e}_{t+1}(\mathbf{a}_t(m_t) \mathcal{R}_{t+1}) \left(\mathbf{R} \mathbf{a}_t(m_t)\right)\right)^{-\rho} \right]$$

and we know from L'Hôpital's rule that $\lim_{m_t \to \infty} e_t(m_t) = \underline{\kappa}_t$, and $\lim_{m_t \to \infty} e_{t+1}(a_t(m_t)\mathcal{R}_{t+1}) = \underline{\kappa}_{t+1}$ so a further limit of the Euler equation is

$$\begin{array}{rcl} \left(m_t \underline{\kappa}_t\right)^{-\rho} & = & \beta \, \mathrm{R} \Big(\underline{\kappa}_{t+1} \mathrm{R} (1-\underline{\kappa}_t) m_t \Big)^{-\rho} \\ \underline{\mathrm{R}}^{-1} \underline{\mathbf{D}} & \underline{\kappa}_t & = & (1-\underline{\kappa}_t) \underline{\kappa}_{t+1} \\ \underline{=} \underline{\mathbf{D}}_{\mathrm{R} = (1-\underline{\kappa})} \end{array}$$

and the same sequence of derivations used above yields the conclusion that if the RIC $0 \le \mathbf{p}_R < 1$ holds, then a recursive formula for the minimal marginal propensity to consume is given by

$$\underline{\kappa}_{t}^{-1} = 1 + \underline{\kappa}_{t+1}^{-1} \mathbf{p}_{R} \tag{3}$$

so that $(\{\underline{\kappa}_{T-n}^{-1}\})_{n=0}^{\infty}$ is also an increasing convergent sequence, and we define

$$\underline{\kappa}^{-1} \equiv \lim_{n \uparrow \infty} \kappa_{T-n}^{-1} \tag{4}$$

as the limiting (inverse) marginal MPC. If the RIC does *not* hold, then $\lim_{n\to\infty} \underline{\kappa}_{T-n}^{-1} = \infty$ and so the limiting MPC is $\underline{\kappa} = 0$.

For the purpose of constructing the limiting perfect foresight consumption function, it is useful further to note that the PDV of consumption is given by

$$c_t \underbrace{\left(1 + \mathbf{P}_{\mathsf{R}} + \mathbf{P}_{\mathsf{R}}^2 + \cdots\right)}_{=1 + \mathbf{P}_{\mathsf{R}}(1 + \mathbf{P}_{\mathsf{R}} \underbrace{\kappa_{t+1}^{-1}}_{t, t}) \dots} = c_t \underbrace{\kappa_{T-n}^{-1}}_{=1 + \mathbf{P}_{\mathsf{R}}(1 + \mathbf{P}_{\mathsf{R}} \underbrace{\kappa_{t+1}^{-1}}_{t, t}) \dots}$$

which, combined with the intertemporal budget constraint, yields the usual formula for the perfect foresight consumption function:

$$c_t = (b_t + h_t)\underline{\kappa}_t \tag{5}$$
