## 1 The Limiting MPC's

For  $m_t > 0$  we can define  $e_t(m_t) = c_t(m_t)/m_t$  and  $a_t(m_t) = m_t - c_t(m_t)$  and the Euler equation (6) can be rewritten

$$e_{t}(m_{t})^{-\rho} = \beta R \mathbb{E}_{t} \left[ \left( e_{t+1}(m_{t+1}) \left( \frac{\underbrace{\mathsf{Ra}_{t}(m_{t}) + \mathbf{\Phi}_{t+1} \boldsymbol{\xi}_{t+1}}}{\mathsf{Ra}_{t}(m_{t}) + \mathbf{\Phi}_{t+1} \boldsymbol{\xi}_{t+1}} \right) \right)^{-\rho} \right]$$

$$= (1 - \wp) \beta R m_{t}^{\rho} \mathbb{E}_{t} \left[ \left( e_{t+1}(m_{t+1}) m_{t+1} \mathbf{\Phi}_{t+1} \right)^{-\rho} | \boldsymbol{\xi}_{t+1} > 0 \right]$$

$$+ \wp \beta R^{1-\rho} \mathbb{E}_{t} \left[ \left( e_{t+1}(\mathcal{R}_{t+1} \mathbf{a}_{t}(m_{t})) \frac{m_{t} - c_{t}(m_{t})}{m_{t}} \right)^{-\rho} | \boldsymbol{\xi}_{t+1} = 0 \right].$$

Consider the first conditional expectation in (6), recalling that if  $\xi_{t+1} > 0$  then  $\xi_{t+1} \equiv \theta_{t+1}/(1-\wp)$ . Since  $\lim_{m\downarrow 0} \mathbf{a}_t(m) = 0$ ,  $\mathbb{E}_t[(\mathbf{e}_{t+1}(m_{t+1})m_{t+1}\mathbf{\Phi}_{t+1})^{-\rho} \mid \boldsymbol{\xi}_{t+1} > 0]$  is contained within bounds defined by  $(\mathbf{e}_{t+1}(\boldsymbol{\theta}/(1-\wp))\mathbf{\Phi}\underline{\boldsymbol{\Psi}}\boldsymbol{\theta}/(1-\wp))^{-\rho}$  and  $(\mathbf{e}_{t+1}(\boldsymbol{\theta}/(1-\wp))\mathbf{\Phi}\underline{\boldsymbol{\Psi}}\boldsymbol{\theta}/(1-\wp))^{-\rho}$  both of which are finite numbers, implying that the whole term multiplied by  $(1-\wp)$  goes to zero as  $m_t^\rho$  goes to zero. As  $m_t \downarrow 0$  the expectation in the other term goes to  $\bar{\kappa}_{t+1}^{-\rho}(1-\bar{\kappa}_t)^{-\rho}$ . (This follows from the strict concavity and differentiability of the consumption function.) It follows that the limiting  $\bar{\kappa}_t$  satisfies  $\bar{\kappa}_t^{-\rho} = \beta \wp \mathsf{R}^{1-\rho} \bar{\kappa}_{t+1}^{-\rho} (1-\bar{\kappa}_t)^{-\rho}$ . Exponentiating by  $\rho$ , we can conclude that

$$\bar{\kappa}_{t} = \wp^{-1/\rho} (\beta \mathsf{R})^{-1/\rho} \mathsf{R} (1 - \bar{\kappa}_{t}) \bar{\kappa}_{t+1}$$

$$\underbrace{\wp^{1/\rho} \, \mathsf{R}^{-1} (\beta \mathsf{R})^{1/\rho}}_{\equiv \wp^{1/\rho} \mathbf{p}_{\mathsf{R}}} \bar{\kappa}_{t} = (1 - \bar{\kappa}_{t}) \bar{\kappa}_{t+1}$$

which yields a useful recursive formula for the maximal marginal propensity to consume:

$$(\wp^{1/\rho} \mathbf{P}_{\mathsf{R}} \bar{\kappa}_t)^{-1} = (1 - \bar{\kappa}_t)^{-1} \bar{\kappa}_{t+1}^{-1}$$
$$\bar{\kappa}_t^{-1} (1 - \bar{\kappa}_t) = \wp^{1/\rho} \mathbf{P}_{\mathsf{R}} \bar{\kappa}_{t+1}^{-1}$$
$$\bar{\kappa}_t^{-1} = 1 + \wp^{1/\rho} \mathbf{P}_{\mathsf{R}} \bar{\kappa}_{t+1}^{-1}.$$

As noted in the main text, we need the WRIC (31) for this to be a convergent sequence:

$$0 \le \wp^{1/\rho} \mathbf{p}_{\mathsf{R}} < 1,\tag{1}$$

Since  $\bar{\kappa}_T = 1$ , iterating (1) backward to infinity (because we are interested in the limiting consumption function) we obtain:

$$\lim_{n \to \infty} \bar{\kappa}_{T-n} = \bar{\kappa} \equiv 1 - \wp^{1/\rho} \mathbf{P}_{\mathsf{R}}$$
 (2)

and we will therefore call  $\bar{\kappa}$  the 'limiting maximal MPC.'

The minimal MPC's are obtained by considering the case where  $m_t \uparrow \infty$ . If the FHWC holds, then as  $m_t \uparrow \infty$  the proportion of current and future consumption that will be financed out of capital approaches 1. Thus, the terms involving  $\xi_{t+1}$  in (1) can

be neglected, leading to a revised limiting Euler equation

$$(m_t \mathbf{e}_t(m_t))^{-\rho} = \beta \mathsf{R} \, \mathbb{E}_t \left[ \left( \mathbf{e}_{t+1}(\mathbf{a}_t(m_t) \mathcal{R}_{t+1}) \left( \mathsf{R} \mathbf{a}_t(m_t) \right) \right)^{-\rho} \right]$$

and using L'Hôpital's rule  $\lim_{m_t\to\infty} e_t(m_t) = \underline{\kappa}_t$ , and  $\lim_{m_t\to\infty} e_{t+1}(a_t(m_t)\mathcal{R}_{t+1}) = \underline{\kappa}_{t+1}$  so a further limit of the Euler equation is

$$(m_t \underline{\kappa}_t)^{-\rho} = \beta \mathsf{R} \big( \underline{\kappa}_{t+1} \mathsf{R} (1 - \underline{\kappa}_t) m_t \big)^{-\rho}$$

$$\underline{\mathsf{R}}^{-1} \underline{\mathbf{b}}_{\mathsf{R} = (1 - \underline{\kappa})} \underline{\kappa}_t = (1 - \underline{\kappa}_t) \underline{\kappa}_{t+1}$$

and the same sequence of derivations used above yields the conclusion that if the RIC  $0 \le \mathbf{p}_R < 1$  holds, then a recursive formula for the minimal marginal propensity to consume is given by

$$\underline{\kappa}_t^{-1} = 1 + \underline{\kappa}_{t+1}^{-1} \mathbf{p}_{\mathsf{R}} \tag{3}$$

so that  $(\{\underline{\kappa}_{T-n}^{-1}\})_{n=0}^{\infty}$  is also an increasing convergent sequence, and we define

$$\underline{\kappa}^{-1} \equiv \lim_{n \uparrow \infty} \kappa_{T-n}^{-1} \tag{4}$$

as the limiting (inverse) marginal MPC. If the RIC does not hold, then  $\lim_{n\to\infty} \underline{\kappa}_{T-n}^{-1} = \infty$  and so the limiting MPC is  $\underline{\kappa} = 0$ .

For the purpose of constructing the limiting perfect foresight consumption function, it is useful further to note that the PDV of consumption is given by

$$c_t \underbrace{\left(1 + \mathbf{p}_{\mathsf{R}} + \mathbf{p}_{\mathsf{R}}^2 + \cdots\right)}_{=1 + \mathbf{p}_{\mathsf{R}}(1 + \mathbf{p}_{\mathsf{R}}\underline{\kappa}_{t+2}^{-1}) \dots} = c_t \underline{\kappa}_{T-n}^{-1}.$$

which, combined with the intertemporal budget constraint, yields the usual formula for the perfect foresight consumption function:

$$c_t = (b_t + h_t)\underline{\kappa}_t \tag{5}$$
